### 1 Introduction

This report discusses and presents a replication of a selection of findings from [2] as well as an empirical application of the methods covered. [2] discusses in-sample prediction and out-of-sample forecasting in regressions with many exogenous predictors based on four dimension-reduction devices: principal components (PCA), ridge, Landweber Fridman (LF), and partial least squares (PLS). Each involves a regularization or tuning parameter that is selected through generalized cross validation (GCV) or Mallows Cp. Following [2] we evaluate these estimators in a monte carlo simulation framework with 6 different data generating processes (DGP).

#### 2 Factor Models in Economics

Factor models attempt to explain panels of data in terms of a smaller number of common factors that apply to each of the variables in the dataset. In the case of high dimensional data, factor models are a useful tool to reduce the dimensionality of the dataset, making estimation possible where the dataset would have been rank deficient before. A factor model on panel data can be represented as

$$\underbrace{X}_{(T\times N)} = \underbrace{F}_{(T\times r)} \underbrace{\Lambda'}_{(r\times N)} + \underbrace{\xi}_{(T\times N)}$$

where X denotes the matrix of observations, F the underlying factors and  $\Lambda$  the corresponding factor loadings.  $\xi$  is an idiosyncratic shock.

Additionally, through dimensionality reduction, factor models can find the most important variables that effect the outcome variables. For factor models in general, a crucial part of the estimation procedure is determining the number of factors to use. This is the context that [2] is set in. The parameter used to select the number of factors in a factor model is also known as the regularization parameter. [2] run simulations to analyze each of the different dimension reduction devices.

### 3 Data Generating Process

To study how accurate each estimation method is, [2] simulate six different data generating processes, both in the large and small sample cases. In the large sample case, the size of the data set is N=200 and T=500. In the small sample case, the size is N=100 and T=50

- DGP 1 (Few Factors Structure):
   θ is the (r × 1) vector of ones, r = 4 and r<sub>max</sub> = r + 10
   DGP 2 (Many Factors Structure):
   θ is the (r × 1) vector of ones, r = 50 and r<sub>max</sub> = min(N, T/2)
   DGP 3 (Five Factors but only One Relevant):
- ▷ DGP 3 (Five Factors but only One Relevant):  $\theta = (1, 0_{1\times 4}), r = 5 \text{ and } r_{max} = min(r + 10, min(N, \frac{T}{2}))$

$$F = [F_1, F_2']' \text{ and } F \times F' = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 & 0 \\ 0 & 0 & 3 & 0 & 0 \\ 0 & 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 0 & 4 \end{bmatrix}$$

 $y = \hat{F}\theta + \nu$  where  $\hat{F}$  is generated from X equation in DGP 3, and  $\sigma_{\nu} = 0.1$ 

▷ DGP 4 ( $x_t$  Has a Factor Structure but Unrelated to  $y_t$ ):  $\theta$  is a vector of zeros with dimension ( $r \times 1$ ). r = 5,  $r_{max} = r + 10$ .  $F \times F'$  is defined

▷ DGP 5 (Eigenvalues Declining Slowly):

 $\theta$  is an  $(N \times 1)$  vector of ones. r = N,  $r_{max} = min(N, \frac{T}{2})$ .

 $\Lambda = M \odot \xi$ , with  $\xi \sim (N \times N)$  matrix of iidN(0,1)

$$M \sim (N \times N) = \begin{bmatrix} \frac{1}{2} & \frac{1}{2} & \cdots & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} & \cdots & \frac{1}{2} \\ \vdots & \vdots & \vdots & \vdots \\ \frac{1}{N} & \frac{1}{N} & \cdots & \frac{1}{N} \end{bmatrix}$$

 $\,\triangleright\,$  DGP 6 (Near Factor Model):

$$\theta = 1, r = 1, r_{max} = r + 10, \Lambda' = \frac{1}{\sqrt{N}} 1_{r \times N}$$

#### 4 Estimation Methods

#### 4.1 Notation

as in DGP 3.

In matrix notation the model is

$$y = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_T \end{pmatrix}, X = \begin{pmatrix} x'_1 \\ x'_2 \\ \vdots \\ x'_T \end{pmatrix}, \varepsilon = \begin{pmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \vdots \\ \varepsilon_T \end{pmatrix}$$

where y is a  $(T \times 1)$  vector, X is a  $(T \times N)$  matrix of predictors and  $\varepsilon$  is a  $(T \times 1)$  vector.

We then write

$$S_{xx} = \frac{X^T X}{T}$$
$$S_{xy} = \frac{X^T y}{T}$$

and  $M_T^{\alpha}$  as the projection matrix of y onto the factors of X.  $\hat{\psi}_j$  is the  $j^{th}$  orthonormalized eigenvector of  $\frac{XX^T}{T}$ . Moreover we denote as  $\alpha$  the choice of penalty parameter which is obtained from one of the selection methods discussed in section 5.

We can then express the estimators as follows:

▶ Ridge Estimator:

$$\widehat{y} = M_T^{\alpha} y = X(S_{xx} + \alpha I)^{-1} S_{xy}$$

where I is the  $(N \times N)$  identity matrix.

▶ LF Estimator:

$$\widehat{y} = M_T^{\alpha} y = X \sum_{j=1}^{\min(N,T)} \frac{\left(1 - \left(1 - d\widehat{\lambda}_j^2\right)^{1/\alpha}\right)}{\widehat{\lambda}_j^2} \left\langle y, \hat{\psi}_j \right\rangle_T \frac{X' \hat{\psi}_j}{T}$$

Here d denotes XXXX. We follow [2] and choose  $d = 0.018/max(\lambda^2)$ . XXXXX WHAT IS NOW LAMBDA SQ AGAIN XXXX.

▷ Spectral Cutoff/Principal Components Estimator:

$$\widehat{y} = M_T^{\alpha} y = \widehat{\Psi} \left( \widehat{\Psi}' \widehat{\Psi} \right)^{-1} \widehat{\Psi}' y$$
where 
$$\widehat{\Psi} = \left[ \widehat{\psi}_1 \left| \widehat{\psi}_2 \right| \dots \right| \widehat{\psi}_k \right]$$

XXX Do we have to say something here about the fact that they are estimated? XXX

▶ Partial Least Squares Estimator:

$$\widehat{y} = M_T^{\alpha} y = X V_k \left( V_k' X' X V_k \right)^{-1} V_k' X' y$$
 where  $V_k = \left( X' y, \quad (X' X) X' y, \dots, (X' X)^{k-1} X' y \right)$ 

### 4.2 SIMPLS Algorithm

Notably we divert from [2] to the extent that we implement PLS via the so called SIMPS algorithm.

$$\begin{split} S &= X^T y \\ &\text{for } i \in 1:k \\ &\text{if } i = 1, [u, s, v] = svd(S) \\ &\text{if } i > 1, [u, s, v] = svd(S - (P_k[:, i-1](P_k[:, i-1]^T P_k[:, i-1])^{-1} P_k[:, i-1]^T S)) \\ &T_k[:, i-1] = X R_k[:, i-1] \\ &P_k[:, i-1] = \frac{X^T T_k[:, i-1]}{T_k[:, i-1]^T T_k[:, i-1]} \\ &\widehat{y} = M_T^{\alpha} y = X R_k (T_k^T T_k)^{-1} T_k^T y \end{split}$$

#### 5 Selection Methods

As outlined above the choice of regularization parameter is crucial. We hence implement selection on three criteria.

▷ Generalized Cross Validation (GCV):

$$\hat{\alpha} = \arg\min_{\alpha \in A_T} \frac{T^{-1} \|y - M_T^{\alpha} y\|^2}{(1 - T^{-1} \operatorname{tr}(M_T^{\alpha}))^2}$$

▶ Mallows' Criterion:

$$\hat{\alpha} = \arg\min_{\alpha \in A_T} T^{-1} \|y - M_T^{\alpha} y\|^2 + 2\widehat{\sigma}_{\varepsilon}^2 T^{-1} \operatorname{tr} (M_T^{\alpha})$$

where  $\hat{\sigma}_{\epsilon}^2$  is a consistent estimator of the variance of  $\epsilon$ . In practice this translates to the variance of  $\epsilon$  being taken from the errors of the largest model, or from the model with all regressors in the case of PCA.

▶ Leave-one-out Cross Validation (LOO-CV):

$$\hat{\alpha} = \arg\min_{\alpha \in A_T} \frac{1}{T} \sum_{t=1}^{T} \left( \frac{y_i - \hat{y}_{i,\alpha}}{1 - M_T^{\alpha}[ii]} \right)^2$$

XXX Can we rewrite the predicted values as the usual Mty? XXX

Note that for PC tr  $(M_T^{\alpha}) = k$ , i.e. the number of factors. As the trace can be seen as a measure for the effective degrees of freedom which guides the penalty parameter selection we also report it in the output tables (XXX IS THIS CORRECT?? XXX). Moreover, we only use LOO-CV for PLS.

#### 6 Simulation Results

We run simulations of the six DGPs outlined in section 3 for a small sample (N = 100, T = 50) and a large sample (N = 200, T = 500). Due to computational limitations we only ran 25 simulations for each of the DGPs in the large sample.<sup>1</sup>

XXXX DISCUSSION OF FINDINGS XXXX

<sup>&</sup>lt;sup>1</sup>For the small sample our personal machines provided sufficient computing power to execute 1000 simulations per DGP.

### 7 Empirical Application

#### 7.1 Introduction and Data

Building on the long history of machine learning in forecasting macroeconomic variables<sup>2</sup> we use the Federal Reserve Bank's monthly database (FRED-MD) to apply the estimators discussed above on real data.<sup>3</sup> This database was established for empirical analysis that requires 'big data' and hence constitutes an ideal environment to employ the methods discussed above. We took inspiration from the work of Coulombe et al. (2020) but limit ourselves to PC, Ridge, PLS and LF. The dataset contains 134 monthly US macroeconomic and financial indicators observed from January 1959 to January 2021. An overview of all variables is given in the appendix. Following Coulombe et al. (2020) we predict three indicators which are of key economic interest, namely Industrial Production (IND-PRO), Unemployment Rate (UNRATE), and housing starts (HOUST).<sup>4</sup> For each of these variables of interest  $Y_t$  we follow Coulombe et al (2020) in defining the forecast objective as

$$y_{t+h} = (1/h)ln(Y_{t+h}/Y_t)$$

where h denotes the number of periods ahead. This allows us to assess the performance of our predictive methods for further periods ahead. Given the nature of the data we expect the underlying factor structure to be similar to DGP XXXXXXXXX

#### 7.2 Evaluation

We evaluate the performance of our methods on the out of sample MSE. To be able to compute this metric we split our data into a training and a test set where the former spans all observations from ... to ... amounting to 80% of the data. Denoting N the number of observations in the test set we calculate the MSE as

$$MSE = \frac{1}{N} \sum_{i=1}^{N} (Y_i - \hat{Y}_i)^2$$

where  $\widehat{Y}_i = \widehat{\Psi}\widehat{\delta}_{pc}$  for PCA and  $\widehat{Y}_i = X_{test}\widehat{\delta}_m, m \in \{R, LF, PLS\}$  for all other models.

We conduct forecasts for  $h = \{1, 3, 9\}$  periods ahead. Given the simulation results we expect Ridge to deliver the best results, here defined as yielding the smallest out of sample MSE. Subsequently we report results similar to the simulation framework; we provide tables showing for each combination of estimator and parameter selection method the chosen penalty parameter/the number of factors as well as the degrees of freedom and the resulting out of sample MSE for h = 1. Moreover, we visualize the out of sample MSE to ease comparison across methods and settings.

 $<sup>^2</sup>$ See e.g. ...

<sup>&</sup>lt;sup>3</sup>Unfortunately we were unable to use (1) Gu et al. (2020) as TSE does not have access to WDRS returns, (2) as only data on the resulting factors is available or (3) as they do not offer any replication data.

<sup>&</sup>lt;sup>4</sup>Fortunately McCracken and Ng (2016), the accompanying paper of the dataset, outlines a transformation method for each variable to achieve stationarity. We apply those transformations in our data preparation.

#### 7.3 Results and Discussion

From tables 1 to 3 we can immediately see that the estimated factor structure as well as the chosen penalty parameters are remarkably stable across both selection criteria and variables of interest. We cautiously take this as indication for the underlying macro data to indeed exhibit a stable factor structure, i.e. that economic variables are driven by a set of common underlying factors. [] The number of estimated factors ranges from 9 to 15 depending on the setting and choice of method, which is in line with the literature []. In terms of forecasting power, we can see that LF yields the smallest out of sample MSE for h=1 across all variables of interest. The difference to Ridge is, however, close to negligible.

Table 1:  $Y_t = INDPRO$ 

Method	OOS MSE, $h = 1$	alpha/k	DOF
LF: GCV LF: Mallow PC: GCV PC: Mallow PLS: GCV PLS: Mallow Ridge: GCV	0.000126 0.000126 0.000162 0.000162 0.002139 0.002139 0.000130	0.0001 0.0001 13.0000 15.0000 15.0000 0.1170	14.532053 14.532053 13.000000 15.000000 15.000000 15.000000 20.074885
Ridge: Mallow	0.000130	0.1170	20.074885

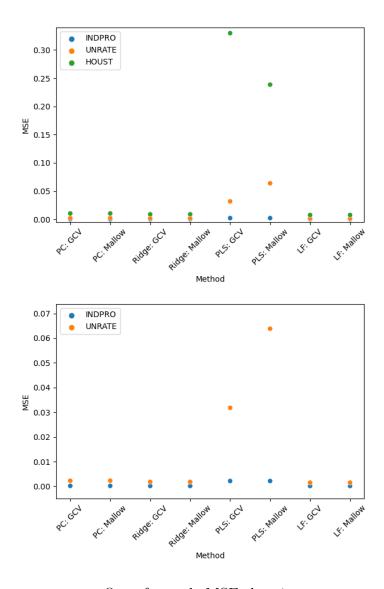

Table 2:  $Y_t = UNRATE$ 

Method	OOS MSE, $h = 1$	alpha/k	DOF
LF: GCV LF: Mallow PC: GCV PC: Mallow PLS: GCV PLS: Mallow	0.001488 0.001488 0.002247 0.002276 0.031782 0.063822	0.0001 0.0001 9.0000 15.0000 13.0000 15.0000	14.418940 14.418940 9.000000 15.000000 13.000000 15.000000
Ridge: GCV Ridge: Mallow	$0.001779 \\ 0.001779$	$0.1170 \\ 0.1170$	$\begin{array}{c} 20.008091 \\ 20.008091 \end{array}$

Table 3:  $Y_t = HOUST$ 

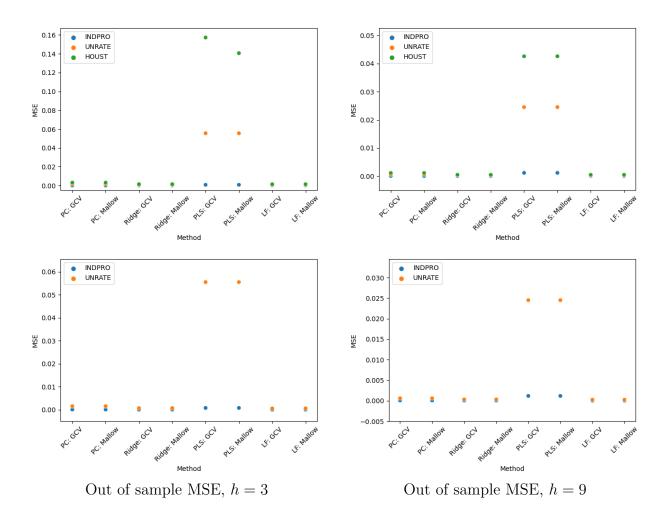

Method	OOS MSE, $h = 1$	alpha/k	DOF
LF: GCV LF: Mallow PC: GCV PC: Mallow PLS: GCV PLS: Mallow Ridge: GCV	0.007627 0.007627 0.010409 0.010409 0.329750 0.238590 0.008906	0.0001 0.0001 15.0000 15.0000 11.0000 15.0000 0.1170	14.441119 14.441119 15.000000 15.000000 11.000000 15.000000 20.052968
Ridge: Mallow	0.008906	$0.1170 \\ 0.1170$	20.052968

Comparing the performance across variables we make the interesting finding that the PLS performs very poorly when predicting HOUST. We therefore report for each

Out of sample MSE, h = 1

time horizon also the subset of only *INDPRO* and *UNRATE* to increase readability. Generally PLS yields the highest out of sample MSE while Ridge and LF perform best. This is somewhat surprising as the simulation results did not indicate a similar pattern XXX CHECK THIS XXX. In line with the findings of Coulombe et al (2020) we observe that the performance increases for further periods ahead.
